# Introduction

## What are “data-driven” classes?

- All classes are data-driven in some sense.
- Data-driven classes are classes defined by dynamic information.
  - Classes which modify or create their behavior based on state (data).
  - Classes not (completely) defined by source or object code

Data-Driven Programming in XQuery

# Introduction

## What is Data-Driven programming?

### Wikipedia

“In computer programming, data-driven programming is a programming paradigm in which the program statements describe the data to be matched and the processing required rather than defining a sequence of steps to be taken.[1] Standard examples of data-driven languages are the text-processing languages sed and AWK,[1] where the data is a sequence of lines in an input stream – these are thus also known as line-oriented languages – and pattern matching is primarily done via regular expressions or line numbers.”

# Introduction

## What is Data-Driven programming?

### Data-oriented Design

“If the ultimate result of an application is data, and all input can be represented by data, and it is recognised that all data transforms are not performed in a vacuum, then a software development methodology can be founded on these principles, the principles of understanding the data, and how to transform it given some knowledge of how a machine will do what it needs to do with data of this quantity, frequency, and its statistical qualities. Given this basis, we can build up a set of founding statements about what makes a methodology data-oriented.”

# Functional XQuery

## The magic of higher-order functions

The `f:transform()` function in [hangman-hof.xq](#):

```
(: Some high order functions magic :)
declare function f:transform($rules as function(*)*) as function(*) {
    function($node as node(), $transform as function(*)) as node()? {
        if (head($rules)('predicate')($node))
            then head($rules)('action')($node, $transform)
        else if (exists(tail($rules)))
            then f:transform(tail($rules))($node, $transform)
        else ()
    }
};
```

# Functional XQuery

## Conclusion

- Higher-order functions do facilitate data-driven programming in XQuery.
- Maps are missed in XQuery 3.0 but can be simulated.
- transform.xq gives you all you need but you can also easily write your own mechanism.
- Good old if/then/else and recursion isn't that awful after all!

## Acknowledgments

Thanks to :

- Tony Graham, Patrick Durusau and my three anonymous reviewers for their reviews, comments, corrections, questions and suggestions.
- John Snelson for his very inspiring transform.xq.
- George Bina for pushing me into dita.
- XML London for this gathering.
